PHYSICAL PROPERTIES VS. CHEMICAL PROPERTIES

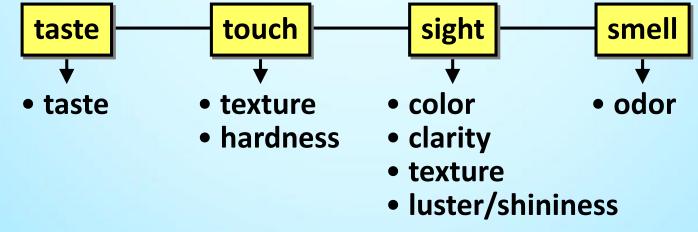

Physical Property:

- A property of a substance that can be observed or measured <u>without changing</u> the chemical identity of the substance.
 - e.g. color, state of matter

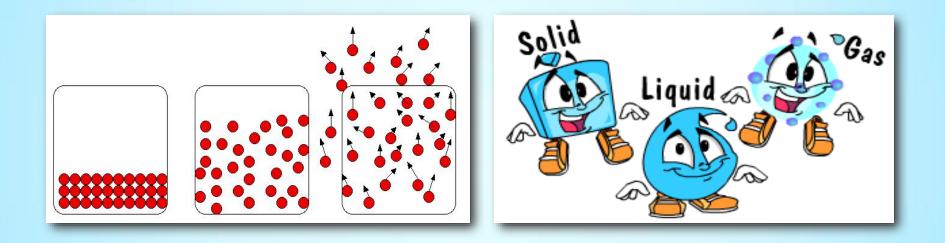

Chemical Property:

 A property of a substance that describes <u>how it reacts</u> to other substances and <u>changes its chemical</u> <u>identity</u> as a result.
 e.g. combustibility

Which properties can you detect with only your senses?

<u>State of Matter</u>: The property of a substance that determines whether or not it is a <u>liquid</u>, <u>solid</u> or <u>gas</u>.

There are three states of matter. Water in a lake is found in the <u>liquid</u> state, water in your ice cube tray is found in the <u>solid</u> state, and water in steam is found in the <u>gas</u> state.

Taste: The property of a substance that describes how it affects the **taste receptors** otherwise known as **taste buds**.

Sugar tastessweetand lemons tastesour. Nothing in a chemistry lab shouldever betasted. Even if one of theingredients is a common food item, once it is used fora lab, it is considered potentiallycontaminated

Odor: The property of a substance that describes how it affects the **olfactory (smell) receptors**.

Old dirty gym socks smell <u>bad</u> and roses smell <u>good</u>. Never <u>smell</u> anything in a chemistry lab unless instructed to do so. If smelling a substance, the <u>hand-waving</u> method should be used to sniff it.

The property of a substance that describes how it affects the <u>light sensing receptors</u> in your <u>eyes / retina</u> when that substance <u>reflects</u> different <u>wavelengths</u> of light.

A fire truck is <u>red</u> but the sky on a sunny day is <u>blue</u>. The leaves on the trees in the summer are <u>green</u>, but the color of the sun is <u>yellow</u>. The color of an orange is <u>orange</u>!

Color:

Luster: The property of a substance that describes how <u>shiny</u> or <u>lustrous</u> it is.

A piece of paper is <u>dull</u> because it does not reflect much light, but the chrome on a car is <u>lustrous / shiny</u> because it reflects a lot of light. Another dull thing is <u>an eraser</u> and another shiny thing is <u>a spoon</u>.

<u>Clarity</u>: The property of a substance that describes how much light can pass through it.

A piece of glass is <u>transparent</u>, meaning that it lets all the light pass through it, maple syrup is <u>translucent</u> because it lets some light through it, and mud is <u>opaque</u> because it lets no light pass through it.

<u>Texture</u>: The property of a substance that describes how the <u>surface</u> of a substance <u>feels</u>.

The surface of a bowl feels <u>smooth</u> but the surface of the cement sidewalk feels <u>rough</u>. The fur of a cat feels <u>soft/fluffy</u>. The surface of an eraser feels <u>rough/tacky</u>.

<u>Hardness</u>: The property of a substance that describes how difficult it is to <u>scratch</u> its surface.

On Mohs hardness scale of minerals, a <u>diamond</u> is the hardest known substance on Earth with a hardness level of <u>10</u>. An emerald is also hard but it has a hardness level of <u>7.5</u>.

Solubility: The property of a substance that describes how easily it **dissolves** when mixed with another substance.

Water and vinegar mix together completely and therefore, vinegar is <u>soluble</u> in water. Salt is also <u>soluble</u> in water because it will dissolve completely in water. Neither oil nor sand will dissolve in water, and that is why they are considered <u>insoluble</u> in water.

Viscosity: The property of a substance that describes how easily it can <u>pour</u> or how <u>thick</u> it is.

Water is <u>less</u> viscous than oil, and that is why it pours out of its container more easily than oil does. Ketchup is <u>more</u> viscous than oil, and that is why it's <u>harder</u> for it to pour out of its container.

Malleability:

The property of a substance that describes its ability be <u>bent</u> or <u>hammered</u> into a <u>thin sheet</u> without <u>breaking</u>.

Aluminumis very malleable and that is why we use it tomake foil to wrap our food. Other substances, like glass, arenotmalleable because it would break instead ofchange shape. Wood is not malleable , while copper ismalleable .

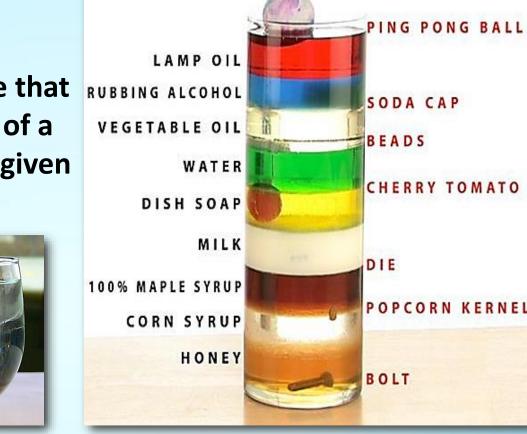

Ductility: The property of a substance that describes its ability to be drawn into a <u>thin wire</u> without <u>breaking</u>.

Many metals like <u>copper</u> and <u>gold</u> can easily be drawn into a thin wire. Substances like water and cement are not <u>ductile</u>.

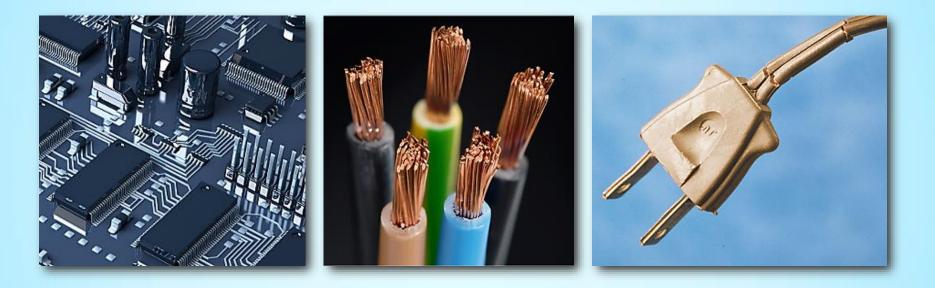

Density:

The property of a substance that describes how much <u>mass</u> of a substance is contained in a given <u>volume</u> of space of that substance.

Rubber islessdense than water and that is why itwill float on water. A penny ismoredense than waterand that is why it will sink to the bottom of the water. Water initssoliditssolidstate is less dense than water in itsliquidstate. That is why ice floats on water.

Electrical The property of a substance that is a measure of **Conductivity:** its ability to conduct an **electrical current**.

Copperis agoodelectrical conductor, andthat is why it is used as the main material for the wiring foundin most homes and electronics. Plastic isnotagood conductor of electricity and that is why it is used toinsulateelectrical wires.

Melting Point:

The property of a substance that is the <u>temperature</u> at which it transforms from the <u>solid</u> state into the <u>liquid</u> state.

Boiling Point:

The property of a substance that is the <u>temperature</u> at which it transforms from the **liquid** state into the **gas** state.

The melting point of water is _0 _ °C and theboiling point of water is _100 °C. The meltingpoint of ______ gold _____ is 1063 °C and theboiling ______ point of gold is 2856 °C.

Crystal Form: The property of a substance that describes the **geometrical shapes** that it takes when it forms crystals in its **solid** state.

If you look with a high powered microscope, you can observe that sugar crystals are oblong and slanted at the sides, but the crystal form of salt is shaped more like a <u>cube</u>.

Magnetism: The property of a substance that describes if it is attracted to a magnetic field.

Some substances like steel are <u>attracted</u> to a magnet and therefore are considered <u>magnetic</u>. Substances like glass are <u>not</u> attracted to magnets and are called <u>non-magnetic</u>.

SOME CHEMICAL PROPERTIES OF MATTER

<u>RECALL</u>: A CHEMICAL PROPERTY of a substance describes <u>how it reacts</u> to other substances and how it <u>changes its chemical identity</u> as a result.

CHEMICAL PROPERTIES

Combustibility:

The property of a substance that describes whether or not it will catch on <u>fire</u> in the presence of <u>oxygen</u> and <u>heat</u>.

Glass is not <u>combustible</u>. Dry wood is <u>more</u> combustible than wet wood. <u>Fossil</u> fuels like coal, natural gas, and gasoline are all combustible.

CHEMICAL PROPERTIES

Reactivity with Water:

The property of a substance that describes whether or not it is reactive with <u>water</u>.

water

sodium

Some substances like <u>sodium</u> are very reactive with water, and so they have to be stored in a water-free environment. Even the water vapor in the air can cause a reaction, so these substances must be stored under <u>mineral oil</u>.
